► Constant coefficient equations

$$ay'' + by' + cy = 0$$

Three cases:

1. $b^2 - 4ac > 0$: distinct real roots

Fundamental set of solutions:

$$y_1(t) = e^{r_1 t}, y_2(t) = e^{r_2 t}$$

2. $b^2 - 4ac = 0$: double real root

Fundamental set of solutions:

$$y_1(t) = e^{r_1 t}, y_2(t) = te^{r_1 t}$$

3. $b^2 - 4ac < 0$: complex roots

Fundamental set of solutions:

$$y_1(t) = e^{\alpha t} \cos(\beta t) \quad y_2(t) = e^{\alpha t} \sin(\beta t)$$

Inhomogeneous equations

So far, we have focused on homogeneous equations

$$y'' + p(t)y' + q(t)y = 0 \quad (1)$$

We now turn to inhomogeneous equations

$$y'' + p(t)y' + q(t)y = g(t) \quad (2)$$

Observations:

- ▶ If we can find a single solution $y_p(t)$ to (2) then we can add on the general solution to (1) to create a two parameter family of solutions:

$$y_p(t) + C_1y_1(t) + C_2y_2(t)$$

- ▶ The set $\{y_p(t) + C_1y_1(t), y_p(t) + C_2y_2(t)\}$ is a fundamental set of solutions if $\{y_p, y_1, y_2\}$ are pairwise linearly independent.
- ▶ Main goal: find a particular solution

$$ay'' + by' + cy = g(t)$$

Basic idea: Guess the most general solution that looks like $g(t)$

Examples:

- ▶ If g is a polynomial, guess that is a polynomial with unspecified coefficients
- ▶ If g is an exponential, guess a similar exponential
- ▶ if g contains trigonometric functions, guess a similar combination of trigonometric functions

Given a linear inhomogeneous equation

$$y'' + p(t)y' + q(t)y = g(t)$$

suppose we have the general solution $c_1y_1(t) + c_2y_2(t)$ to the *homogeneous* version of this equation. The main idea is similar to reduction of order: replace the constants with functions of t . i.e. look for solutions of the form

$$u_1(t)y_1(t) + u_2(t)y_2(t)$$

Example:

$$y'' - 2y' - 3y = -3te^{-t}$$

Fundamental set of solutions to homogeneous equation:
 $\{e^{3t}, e^{-t}\}$

Theorem

If the functions p, q and g are continuous on an open interval I , and if the functions y_1 and y_2 are linearly independent solutions of the homogeneous equation

$$y'' + p(t)y' + q(t)y = 0 \quad (3)$$

associated to the inhomogeneous equation

$$y'' + p(t)y' + q(t)y = g(t) \quad (4)$$

then a particular solution of (4) is

$$y_p(t) = -y_1(t) \int_{t_0}^t \frac{y_2(s)g(s)}{W(y_1, y_2, s)} ds + y_2(t) \int_{t_0}^t \frac{y_1(s)g(s)}{W(y_1, y_2, s)} ds$$

where t_0 is any point in I .
