# The Set Up

Consider the general equation

$$\mathbf{x}' = \mathbf{A}\mathbf{x},$$

where  $\mathbf{A}$  is a constant matrix.

- **equilibrium** solutions correspond to solutions of  $\mathbf{A}\mathbf{x} = 0$ .
- $\det \mathbf{A} \neq 0$  if and only if  $\mathbf{x}(t) = 0$  is the only equilibrium solution.
- When  $\det \mathbf{A} \neq 0$  it is interesting to see whether solutions approach or diverge from the equilibrium  $\mathbf{x}(t) = 0$  as  $t \rightarrow \pm\infty$ .

# The Set Up

Let  $\mathbf{A}$  be a  $2 \times 2$  matrix

- a solution  $\mathbf{x}(t) = (x_1(t), x_2(t))$  of

$$\mathbf{x}' = \mathbf{A}\mathbf{x},$$

is a curve in the  $x_1x_2$ -plane.

- $\mathbf{x}'(t) = (x'_1(t), x'_2(t))$  is the velocity vector.
- Plotting  $\mathbf{A}\mathbf{x}$  gives us the **phase plane**.

## The Strategy

Let  $\mathbf{A}$  be a  $2 \times 2$  matrix (with  $\det(\mathbf{A}) \neq 0$ ).

- Suppose  $\mathbf{x}(t) = \zeta e^{rt}$  solves

$$\mathbf{x}' = \mathbf{A}\mathbf{x},$$

where  $\zeta = (\zeta_1, \dots, \zeta_n)^t$ .

- $\mathbf{x}(t) = \zeta e^{rt}$  is a solution if and only if  $\mathbf{A}\zeta = r\zeta$ .

### Moral

Solving  $\mathbf{x}' = \mathbf{A}\mathbf{x}$  is equivalent to finding eigenvalues and eigenvectors of  $\mathbf{A}$ .

## Example 1: Saddle

Let  $\mathbf{A} = \begin{pmatrix} 3 & -2 \\ 2 & -2 \end{pmatrix}$ , then solve

$$\mathbf{x}' = \mathbf{A}\mathbf{x}.$$

- Step 1: Assume solution looks like  $\mathbf{x}(t) = \zeta e^{rt}$ .
- Step 2: Find eigenvalues of  $\mathbf{A}$ .
- Step 3: Find the corresponding eigenvectors.
- Step 4: Find the General Solution

The equilibrium solution  $\mathbf{x}(t) = (0, 0)$  is a **saddle**.

## Example 1: Saddle

## Example 2: Sink

Let  $\mathbf{A} = \begin{pmatrix} -3 & \sqrt{2} \\ \sqrt{2} & -2 \end{pmatrix}$ , then solve

$$\mathbf{x}' = \mathbf{A}\mathbf{x}.$$

- Step 1: Assume solution looks like  $\mathbf{x}(t) = \zeta e^{rt}$ .
- Step 2: Find eigenvalues of  $\mathbf{A}$ .
- Step 3: Find the corresponding eigenvectors.
- Step 4: Find the General Solution

The equilibrium solution  $\mathbf{x}(t) = (0, 0)$  is a **sink**.

## Example 2: Sink

## Example 3: Source

Let  $\mathbf{A} = \begin{pmatrix} 3 & -\sqrt{2} \\ -\sqrt{2} & 2 \end{pmatrix}$ , then solve

$$\mathbf{x}' = \mathbf{A}\mathbf{x}.$$

- Step 1: Assume solution looks like  $\mathbf{x}(t) = \zeta e^{rt}$ .
- Step 2: Find eigenvalues of  $\mathbf{A}$ .
- Step 3: Find the corresponding eigenvectors.
- Step 4: Find the General Solution

The equilibrium solution  $\mathbf{x}(t) = (0, 0)$  is a **source**.

## Example 3: Source

# Equilibrium Points

Consider a  $2 \times 2$  constant coefficient system with two nonzero real, distinct eigenvalues  $\lambda_1, \lambda_2$ .

- If  $\lambda_1 < 0 < \lambda_2$ , then the origin is a **saddle**.
- If  $\lambda_1 < \lambda_2 < 0$ , then the origin is a **sink**. All solutions tend to  $(0, 0)$  as  $t \rightarrow \infty$ , and most tend towards  $(0, 0)$  in the direction of the  $\lambda_2$ -eigenvector. Why?
- If  $0 < \lambda_2 < \lambda_1$ , then  $(0, 0)$  is a **source**. All solutions (except the equil. sol.) go to infinity as  $t \rightarrow \infty$ , and most solution curves *leave* the origin in the direction of the  $\lambda_2$ -eigenvector. Why?

# Equilibrium Points

## Question

What happens if  $\lambda_1 = 0$  and  $\lambda_2 \neq 0$ ?

## Useful Facts

### Theorem

Let  $\mathbf{A}$  be a  $2 \times 2$  matrix with **real** entries and let  $\phi(t)$  be a complex valued solution to

$$\mathbf{x}' = \mathbf{A}\mathbf{x},$$

then

- 1  $\overline{\phi(t)}$  is also a solution
- 2 and, therefore,  $\operatorname{Re}(\phi(t))$  and  $\operatorname{Im}(\phi(t))$  are also solutions.

## Useful Facts

### Theorem

Let  $\mathbf{A}$  be a  $2 \times 2$  matrix with **real** entries and suppose  $\lambda = \mu + i\nu$  ( $\nu \neq 0$ ) is an eigenvalue of  $\mathbf{A}$  with a corresponding eigenvector  $\lambda$ . Then  $\bar{\lambda} = \mu - i\nu$  is an eigenvalue of  $\mathbf{A}$  and  $\bar{\zeta}$  is a corresponding eigenvector.

## Useful Facts

### Theorem

Let  $\mathbf{A}$  be a  $2 \times 2$  real matrix with complex eigenvalues  $\lambda_1 = \mu + i\nu$  and  $\lambda_2 = \mu - i\nu$ , where  $\nu \neq 0$ . Let  $\zeta$  be an eigenvector. Then

- 1  $\zeta = V + iW$ , where  $V, W \in \mathbb{R}^2$  are non-zero.
- 2  $V = \operatorname{Re}(\zeta)$  and  $W = \operatorname{Im}(\zeta)$  are linearly independent vectors. In particular,  $V, W \neq \mathbf{0}$ .

Why?

## A Strategy

Suppose  $\mathbf{A}$  has complex eigenvalues  $\lambda = \mu + i\nu$ ,  $\nu \neq 0$ . To solve  $\mathbf{x}' = \mathbf{A}\mathbf{x}$  we:

- 1 Assume  $\mathbf{x}(t) = e^{\lambda t}\zeta$
- 2 Find eigenvector  $\zeta = \mathbf{V} + i\mathbf{W}$  associated to  $\lambda$
- 3  $\mathbf{x}(t) = e^{\lambda t}\zeta$  is a complex valued solution.
- 4 Then  $\{\text{Re}(\mathbf{x}(t)), \text{Im}(\mathbf{x}(t))\}$  forms a fundamental set of real-valued solutions. **Why?**

## Example I: Real Part Non-Zero

Let  $\mathbf{A} = \begin{pmatrix} -2 & -3 \\ 3 & -2 \end{pmatrix}$ , then solve

$$\mathbf{x}' = \mathbf{A}\mathbf{x}.$$

- Step 1: Assume solution looks like

$$\mathbf{x}(t) = \zeta e^{rt}.$$

- Step 2: Find eigenvalues of  $\mathbf{A}$

$$\lambda_1 = -2 + 3i, \lambda_2 = -2 - 3i$$

- Step 3: Find the corresponding eigenvectors.

$$\zeta_1 = \begin{pmatrix} 1 \\ -i \end{pmatrix}, \zeta_2 = \begin{pmatrix} 1 \\ +i \end{pmatrix}$$

## Example I: Real Part Non-Zero

- Step 4: A non-trivial complex solution is given

$$\phi(t) = e^{\lambda_1 t} \zeta_1 = e^{-2t} \begin{pmatrix} \cos(3t) + i \sin(3t) \\ \sin(3t) - i \cos(3t) \end{pmatrix}$$

- Step 5: The general solution is given by

$$\begin{aligned} \mathbf{x}(t) &= c_1 \operatorname{Re}(\phi(t)) + c_2 \operatorname{Im}(\phi(t)) \\ &= c_1 e^{-2t} \begin{pmatrix} \cos(3t) \\ \sin(3t) \end{pmatrix} + c_2 e^{-2t} \begin{pmatrix} \sin(3t) \\ -\cos(3t) \end{pmatrix} \end{aligned}$$

The equilibrium solution  $\mathbf{x}(t) = (0, 0)$  is a **spiral point**.

## Example I: Real Part Non-Zero

## Example II: Purely Imaginary Eigenvalues

Let  $\mathbf{B} = \begin{pmatrix} 0 & 2 \\ -2 & 0 \end{pmatrix}$ , then solve  $\mathbf{x}' = \mathbf{B}\mathbf{x}$ .

- Step 1: Assume solution looks like

$$\mathbf{x}(t) = \zeta e^{rt}.$$

- Step 2: Find eigenvalues of  $\mathbf{B}$

$$\lambda_1 = 2i, \lambda_2 = -2i.$$

- Step 3: Find the corresponding eigenvectors

$$\zeta_1 = \begin{pmatrix} 1 \\ +i \end{pmatrix}, \zeta_2 = \begin{pmatrix} 1 \\ -i \end{pmatrix}$$

## Example II: Purely Imaginary Eigenvalues

- Step 4: Find Complex Solutions

$$\phi(t) = e^{\lambda_1 t} \zeta_1 = \begin{pmatrix} \cos(2t) + i \sin(2t) \\ -\sin(2t) + i \cos(2t) \end{pmatrix}$$

- Step 5: The General Solution is given by

$$\begin{aligned} \mathbf{x}(t) &= c_1 \operatorname{Re}(\phi(t)) + c_2 \operatorname{Im}(\phi(t)) \\ &= c_1 \begin{pmatrix} \cos(2t) \\ -\sin(2t) \end{pmatrix} + c_2 \begin{pmatrix} \sin(2t) \\ \cos(2t) \end{pmatrix} \end{aligned}$$

The equilibrium solution  $\mathbf{x}(t) = (0, 0)$  is a **center**.

## Example II: Purely Imaginary Eigenvalues

## Equilibrium Points

Consider a  $2 \times 2$  constant coefficient system with complex eigenvalues  $\lambda = \alpha \pm i\beta$  ( $\beta \neq 0$ ).

- If  $\alpha < 0$ , the solutions spiral towards the origin as  $t \rightarrow \infty$  and we say  $(0, 0)$  is a **spiral sink**.
- If  $\alpha > 0$ , the solutions spiral away from the origin as  $t \rightarrow \infty$  and we say  $(0, 0)$  is a **spiral source**.
- If  $\alpha = 0$ , the solutions are periodic and we say  $(0, 0)$  is a **center**.

# Outline

- 1 Homogeneous Linear Systems with Constant Coefficients

  - Preliminaries
  - An Example
  - General Solution

# The Set Up

Let  $\mathbf{A}$  be a  $2 \times 2$  real matrix with one repeated real eigenvalue  $\lambda$ . There are two cases.

- 1  $\lambda$  has two linearly independent eigenvectors  $\zeta_1$  and  $\zeta_2$ .
- 2  $\lambda$  has only one linearly indep. eigenvector  $\zeta$ .

# The Set Up

**Case 1:**  $\lambda$  has two linearly independent eigenvectors  $\zeta_1$  and  $\zeta_2$ .

- General solution is  $\phi(t) = c_1 e^{\lambda t} \zeta_1 + c_2 e^{\lambda t} \zeta_2$ .
- $\lambda > 0$  then origin is a source.  $\lambda < 0$  origin is a sink.

**Case 2:**  $\lambda$  has one linearly independent eigenvector  $\zeta$ .

- $e^{\lambda t} \zeta$  is a non-trivial solution.
- How do you get a fundamental set of solutions? That is, how do we get the general solution? The key will be the existence of a vector  $\eta$  such that

$$(\mathbf{A} - \lambda I)\eta = \zeta.$$

## Example: Repeated Eigenvalue

Let  $\mathbf{A} = \begin{pmatrix} -2 & 1 \\ 0 & -2 \end{pmatrix}$ , then solve  $\mathbf{x}' = \mathbf{A}\mathbf{x}$ .

- There is one eigenvalue of  $\mathbf{A}$ :  $\lambda = -2$
- $\text{mult}_{\text{geom}}(-2) = 1$ . In particular, the eigenvectors associated to  $\lambda = -2$  are all scalar multiples of

$$\zeta = \begin{pmatrix} 1 \\ 0 \end{pmatrix}.$$

- $\mathbf{x}_1(t) = e^{\lambda t}\zeta = e^{-2t} \begin{pmatrix} 1 \\ 0 \end{pmatrix}$  is a non-trivial solution.

## Example: Repeated Eigenvalue

The system  $\mathbf{x}' = \begin{pmatrix} -2 & 1 \\ 0 & -2 \end{pmatrix} \mathbf{x}$  implies

- $\frac{dy}{dt} = -2y$ , hence  $y(t) = y_0 e^{-2t}$
- Then  $\frac{dx}{dt} = -2x + y_0 e^{-2t}$
- So  $x(t) = y_0 t e^{-2t} + x_0 e^{-2t}$ .
- Hence, the general solution is given by

$$\phi(t) = x_0 e^{-2t} \begin{pmatrix} 1 \\ 0 \end{pmatrix} + y_0 \left( e^{-2t} \begin{pmatrix} 0 \\ 1 \end{pmatrix} + t e^{-2t} \begin{pmatrix} 1 \\ 0 \end{pmatrix} \right)$$

- Notice that  $\eta = (0, 1)^t$  satisfies:

$$(\mathbf{A} - (-2)I)\eta = \zeta.$$

## Example: Repeated Eigenvalue

# Useful Facts

## Theorem

Let  $\mathbf{A}$  be a  $2 \times 2$  real matrix with one repeated real eigenvalue  $\lambda$ . And suppose the  $\lambda$ -eigenvectors are of the form  $c\zeta$  for any  $c \neq 0 \in \mathbb{R}$  (i.e.,  $\text{mult}_{\text{geom}}(\lambda) = 1$ ), then there exists a non-zero vector  $\eta$  such that

$$(\mathbf{A} - \lambda\mathbf{I})\eta = \zeta.$$

- It then follows that

$$\mathbf{x}_1(t) = e^{\lambda t}\zeta \text{ and } \mathbf{x}_2(t) = e^{\lambda t}\eta + te^{\lambda t}\zeta$$

form a fundamental set of solutions to the system  $\mathbf{x}' = \mathbf{A}\mathbf{x}$ .

# The Theorem

## Theorem

*Suppose*

$$\mathbf{x}' = \mathbf{A}\mathbf{x}$$

*is a const. coeff.  $2 \times 2$  system where  $\mathbf{A}$  has a repeated eigenvalue  $\lambda$  with **geometric multiplicity 1**. Then the general solution has the form*

$$c_1 e^{\lambda t} \zeta + c_2 (e^{\lambda t} \eta + t e^{\lambda t} \zeta)$$

*where  $\zeta$  is a  $\lambda$ -eigenvector and  $\eta$  satisfies  $(\mathbf{A} - \lambda I)\eta = \zeta$ .*

Equivalently...

## The Theorem (restated)

### Theorem

*Suppose*

$$\mathbf{x}' = \mathbf{A}\mathbf{x}$$

*is a const. coeff.  $2 \times 2$  system where  $\mathbf{A}$  has a repeated eigenvalue  $\lambda$  with **geometric multiplicity 1**. Then the general solution has the form*

$$e^{\lambda t}\hat{\eta} + te^{\lambda t}\hat{\zeta}$$

*where  $\hat{\eta} = (x_0, y_0)$  is an arbitrary initial condition and  $\hat{\zeta} = (\mathbf{A} - \lambda\mathbf{I})\hat{\eta}$ . If  $\hat{\zeta}$  is zero, then  $\hat{\eta}$  is an eigenvector. Otherwise,  $\hat{\zeta}$  is an eigenvector.*

# Exercises

Find the general solution to the system  $\mathbf{x}' = \mathbf{A}\mathbf{x}$ , where

1  $\mathbf{A} = \begin{pmatrix} 1 & -1 \\ 1 & 3 \end{pmatrix}$

2  $\mathbf{A} = \begin{pmatrix} 4 & -1 \\ 1 & 2 \end{pmatrix}$
